The Bellman-Ford Algorithm

Single-Source Shortest
Paths, Revisted

The Single-Source Shortest Path Problem

Input: directed graph $G = (V, E)$, edge lengths c_e for each $e \in E$, source vertex $s \in V$. [can assume no parallel edges]

Goal: for every destination $v \in V$, compute the length of a shortest $s-v$ path.
└─ sum of edge costs

On Dijkstra's Algorithm

Good news: $O(m \log n)$ running time using heaps.

m = number of edges

n = number of vertices

Bad news:

- ① not always correct with negative edge lengths
(e.g., if edges \leftrightarrow financial transactions)
- ② not very distributed (relevant for Internet routing)

Solution: the Bellman-ford algorithm

On Negative Cycles

Question: how to define shortest paths when G has a negative cycle?

Solution #1: compute the shortest $s-v$ path, with cycles allowed.

Problem: undefined (or $-\infty$). [will keep traversing negative cycles]

Solution #2: compute shortest cycle-free $s-v$ path.

Problem: NP-hard (no polynomial algorithm, unless $P=NP$)

Solution #3: (for now) assume input graph has no negative cycles.

Later: will show how to quickly check this condition.

Quiz

Quiz: Suppose the input graph G has no negative cycles. Which of the following is true? [Pick the strongest true statement.] [$n = \#$ of vertices, $m = \#$ of edges]

- ☒ (A) for every v , there is a shortest $s-v$ path with $\leq n-1$ edges.
- ☐ (B) for every v , there is a shortest $s-v$ path with $\leq n$ edges.
- ☐ (C) for every v , there is a shortest $s-v$ path with $\leq m$ edges.
- ☐ (D) a shortest path can have an arbitrarily large number of edges in it.
